

Electric Field and \hat{r}

1 Overview

This activity covers topics in [Section 21.4 of Young and Freedman 2015, 14th Edition](#).

The electric field vector, \vec{E} , is a quantity assigned to a point in space. Given this quantity, we can compute the force on a charge Q will experience if it is placed at that point using the equation $\vec{F} = Q\vec{E}$. The direction of \vec{E} is also the direction a charge will begin to move if released from rest.

To find \vec{E} at any point in space, compute the force \vec{F} due to all other charges on a hypothetical (or “test”) charge q_o at a point where you want to know \vec{E} . To find \vec{E} at that point, divide \vec{F} by q_o .

$$\vec{E} = \frac{\vec{F}}{q_o}$$

2 Example I

Charge q_1 is at $(x, y) = (-a, -a)$. Find the electric field at $(x, y) = (a, a)$ in the form $\vec{E} = E_x\hat{i} + E_y\hat{j}$. Also, find E . (Note that E and $|\vec{E}|$ are used interchangeably.)

Solution

To find the electric field at a point in space, we put a hypothetical “test” charge q_o at that point, compute the force on it due to all other charges, and then use

$$\vec{E} = \frac{\vec{F}}{q_o}$$

The force a positive charge q_1 at $(x, y) = (-a, -a)$ exerts on a positive charge q_2 at $(x, y) = (a, a)$ was computed in a previous activity.

$$\vec{F}_{q_1 \text{ on } q_2} = k \frac{|q_1 q_2|}{8a^2} (\cos 45^\circ \hat{i} + \sin 45^\circ \hat{j})$$

We also found that this equation applies when q_1 and q_2 are both positive or both are negative. If q_1 was positive and q_2 was negative, or vice-versa, we found the sign changed:

$$\vec{F}_{q_1 \text{ on } q_2} = -k \frac{|q_1 q_2|}{8a^2} (\cos 45^\circ \hat{i} + \sin 45^\circ \hat{j})$$

Based on this, we can write a single equation for all possibilities:

$$\vec{F}_{q_1 \text{ on } q_2} = k \frac{q_1 q_2}{8a^2} (\cos 45^\circ \hat{i} + \sin 45^\circ \hat{j})$$

If we replace q_2 with q_o , this is

$$\vec{F}_{q_1 \text{ on } q_o} = k \frac{q_1 q_o}{8a^2} (\cos 45^\circ \hat{i} + \sin 45^\circ \hat{j})$$

The electric field at the location of q_o is then

$$\vec{\mathbf{E}}_{\text{at } (a,a) \text{ due to } q_1} = \frac{\vec{\mathbf{F}}}{q_o} = \frac{kq_1}{8a^2} (\cos 45^\circ \hat{\mathbf{i}} + \sin 45^\circ \hat{\mathbf{j}}) = \frac{kq_1}{8a^2} \left[\frac{1}{\sqrt{2}} \hat{\mathbf{i}} + \frac{1}{\sqrt{2}} \hat{\mathbf{j}} \right],$$

where the fact that $\sin 45^\circ = \cos 45^\circ = 1/\sqrt{2}$ was used. The magnitude is $E = \sqrt{E_x^2 + E_y^2} = k|q_1|/8a^2$

Sign check: When computing electric fields and forces, it is easy to make a sign error. The electric field vector points in the direction a positive charge will move if released there from rest. Suppose q_1 is positive. Our equation predicts that a positive charge released from rest at (a, a) will move up and to the right. Suppose q_1 is negative. Our equation predicts that a positive charge will move down and to the left. This is consistent with the fact that like charges repel and unlike charges attract.

3 Problem I

Charge q_1 is at $(x, y) = (-a, a)$. At $(x, y) = (a, 0)$, find $\vec{\mathbf{E}}$ in the form $\vec{\mathbf{E}} = E_x \hat{\mathbf{i}} + E_y \hat{\mathbf{j}}$. Check signs of the components of $\vec{\mathbf{E}}$ using the technique used in Example I. Also, find E .

4 The $\hat{\mathbf{r}}$ Unit Vector

Previously, when computing the electric force between two charges, you used the formula $F = k|q_1 q_2|/r^2$ to find the magnitude of the force and then used a diagram to write $\vec{\mathbf{F}}$ in the form $\vec{\mathbf{F}} = F_x \hat{\mathbf{i}} + F_y \hat{\mathbf{j}}$. A similar process was used for computing $\vec{\mathbf{E}}$ above (because we calculated $\vec{\mathbf{F}}$ as part of the process). The textbook provides an equation for the electric field that requires a slightly different calculation method.

The equation for the electric field using a unit vector is

$$\vec{\mathbf{E}}_{\text{due to } q_1} = kq_1 \frac{\hat{\mathbf{r}}}{r^2},$$

where $\hat{\mathbf{r}}$ is the unit vector that points from the position of q_1 to the point in space where we want to know $\vec{\mathbf{E}}$, and r is the distance between q_1 and that point.

To find $\hat{\mathbf{r}}$,

1. draw a vector, $\vec{\mathbf{r}}$ from q_1 to the point in space where you want to know $\vec{\mathbf{E}}$;
2. Write $\vec{\mathbf{r}}$ in the form $\vec{\mathbf{r}} = r_x \hat{\mathbf{i}} + r_y \hat{\mathbf{j}}$; then
3. $\hat{\mathbf{r}} = \vec{\mathbf{r}}/r$, where $r = \sqrt{r_x^2 + r_y^2}$.

5 Example II

If q_1 is at $(x, y) = (-a, -a)$, find the electric field at $(x, y) = (a, a)$ using $\vec{\mathbf{E}}_{\text{due to } q_1} = kq_1 \hat{\mathbf{r}}/r^2$. Also, find E .

Solution

The calculation of $\hat{\mathbf{r}}$ is shown in the following diagram.

$$\mathbf{r} = r_x \hat{\mathbf{i}} + r_y \hat{\mathbf{j}} = r \cos 45^\circ \hat{\mathbf{i}} + r \sin 45^\circ \hat{\mathbf{j}}$$

$$\begin{aligned} \hat{\mathbf{r}} &= \frac{\mathbf{r}}{r} \\ &= \frac{r \cos 45^\circ \hat{\mathbf{i}} + r \sin 45^\circ \hat{\mathbf{j}}}{r} \\ &= \cos 45^\circ \hat{\mathbf{i}} + \sin 45^\circ \hat{\mathbf{j}} \end{aligned}$$

Substitution gives

$$\vec{\mathbf{E}}_{\text{at } (a,a) \text{ due to } q_1} = kq_1 \frac{1}{r^2} \hat{\mathbf{r}} = kq_1 \frac{1}{8a^2} (\cos 45^\circ \hat{\mathbf{i}} + \sin 45^\circ \hat{\mathbf{j}}) = \frac{kq_1}{8a^2} \left[\frac{1}{\sqrt{2}} \hat{\mathbf{i}} + \frac{1}{\sqrt{2}} \hat{\mathbf{j}} \right],$$

To calculate $\vec{\mathbf{E}}$, we can use

and plug in $E_x = k \frac{q_1}{8a^2} \frac{1}{\sqrt{2}}$ and $E_y = k \frac{q_1}{8a^2} \frac{1}{\sqrt{2}}$ and use $\sqrt{c^2} = |c|$ (where c is a real number) to show that $E = k|q_1|/8a^2$. There is an easier way. Taking the magnitude of both sides of

7 Problem III - Superposition

In the previous examples, only one charge was responsible for creating the electric field $\vec{\mathbf{E}}$. When there are more charges, superposition can be used to find the total electric field by summing $\vec{\mathbf{E}}$ due to each charge.

Charge $q_1 = +q$ is at $(x, y) = (a, 0)$, charge $q_2 = +q$ is at $(x, y) = (-a, 0)$, and charge $q_3 = -q$ is at $(x, y) = (0, a)$. Assume that q is a positive number.

1. Draw this charge configuration below.

2. Why does it not make sense to ask what the electric *force* is at the origin?

In the following,

3. Find the electric field at the origin due to q_1 . Write your answer in the form $\vec{\mathbf{E}}_1 = E_{x1}\hat{\mathbf{i}} + E_{y1}\hat{\mathbf{j}}$.

4. Find the electric field at the origin due to q_2 . Write your answer in the form $\vec{\mathbf{E}}_2 = E_{x2}\hat{\mathbf{i}} + E_{y2}\hat{\mathbf{j}}$.

5. Find the electric field at the origin due to q_3 . Write your answer in the form $\vec{\mathbf{E}}_3 = E_{x3}\hat{\mathbf{i}} + E_{y3}\hat{\mathbf{j}}$.

6. Find the total electric field at the origin by adding $\vec{\mathbf{E}}_1$, $\vec{\mathbf{E}}_2$, and $\vec{\mathbf{E}}_3$. Write your answer in the form $\vec{\mathbf{E}} = E_x \hat{\mathbf{i}} + E_y \hat{\mathbf{j}}$.

7. Will your answers to 3.–6. change if the problem had asked for the electric field at a different position? If so, which answers?

8. Find the electric field at the origin if charge $q_1 = 2q$ (instead of q).

9. Find the electric field at the origin if charge $q_1 = -2q$ (instead of q).
